### Streszczenie

A comparative study of the luminescent properties of  $\text{SrAl}_4\text{O}_7:\text{Eu}^{3+}(x\%)$  and  $\text{SrAl}_4\text{O}_7:\text{Eu}^{3+}(x\%),\text{Na}^+(x\%)$  ( $x=0.002$  to  $0.1$ ) phosphor powders as a function of activator concentration is reported. Upon UV excitation both series of compounds exhibit strong characteristic red  $\text{Eu}^{3+}$  photoluminescence with a maximum around 611.5 nm, which intensity increases with an increase of activator content. It was found that the luminescence spectra of singly  $\text{Eu}^{3+}$  doped strontium aluminate are much more concentration dependent. As the dopant content increases, the spectra of  $\text{SrAl}_4\text{O}_7:\text{Eu}^{3+}$  show an increased line broadening and the emergence of new emission components. The observed changes in the studied concentration range are due to an increased disorder of  $\text{Eu}^{3+}$  local symmetry induced by the increase in the number of defects in host lattice and by the presence of a new crystalline phase that occurs at the higher dopant content. Charge compensation through  $\text{Na}^+$  co-doping facilitates an incorporation of  $\text{Eu}^{3+}$  into the  $\text{SrAl}_4\text{O}_7$  lattice and leads to a smaller symmetry disorder of activator surroundings as well as a significantly enhanced  $\text{Eu}^{3+}$  luminescence intensity. The largest increase in emission intensity (~6.5 times) was observed for 7%-doped sample. Concentration dependences of the luminescence kinetics of both types of materials are clearly different. It was found that for singly  $\text{Eu}^{3+}$  doped  $\text{SrAl}_4\text{O}_7$  the 5D<sub>0</sub> lifetime shortens with the increase of activator content from 1.8 to 1.4 ms while for  $\text{Na}^+$  co-doped  $\text{SrAl}_4\text{O}_7$  this value does not vary over a range of concentrations and is approximately 1.8 ms.  $\text{SrAl}_4\text{O}_7:\text{Eu}^{3+},\text{Na}^+$  powders are potential candidates to be used as luminescent materials.

### Słowa kluczowe
